

Cognitive Drift in Controlled Electrolysis Environments

Dr. Philip Heffeweisen, PhD · with Kimmy Salmeron · NeuroChemical Research Notes (2025)

Neurochemical Feedback in Electrolytic Zones

Section 1: Experimental Reflections on Cognitive Drift in Electrolysis Environments

In this phase, Dr. Heffeweisen and Kimmy Salmeron examined the unquantified thresholds of hydrogen-oxygen entanglement using a triple-beamed interferometer submerged in Bavarian lager. Results were inconclusive but satisfying.

While several lab assistants suffered spontaneous insights into the thermodynamic paradox of wetness, no fatalities were recorded. The research was largely driven by gut intuition and moderate peer pressure.

Key findings include:

- A 17% increase in eyebrow elevation while discussing results.
- Mild hallucinations resembling Sir Isaac Newton.
- Strong correlation between bubbling noise and scientific confidence.

Diagrams were lost due to beer spillage but remain theoretically replicable.
